

WATER DISPERSION

The Problem

Water contamination of diesel fuel is the biggest threat to diesel engines. All fuels contain some water in suspension, but unlike gasoline, diesel fuel and now biodiesels hold a much larger amount. This water can cause severe problems in water separators (filters), fuel injector tips, and sudden cooling in the engine which may result in shortened engine life and reduced performance, amongst other problems.

Where can water inside the tank go?

There are two types of water in the tank and each has its own way of leaving the tank:

Free Water – is the big mass of water that drops and settles at the bottom of the tank. This water can be drained via the drainage valve or via a pump.

Water in the Solution – Because this water is much smaller in mass than the Free Water, it does not sink to the bottom, so the only way out is the same exit as the fuel. Left untreated, a large part of it will pass through the filters causing problems. Treating it with our Xp3 fuel additive, water will be **dispersed** (*see below*) and will exit the tank along with the fuel without causing any harm to the engine or without reduced performance.

What is water dispersion and how does Xp³ disperse water in the fuel?

Dispersion is the ability to separate and maintain a part infinitely minute, in this case a water molecule, and keep it separated from the rest of the water molecules and suspended in the fuel. What Xp³ does is disperse the water molecules and maintain them separated and suspended without allowing them to form a mass of water. This allows them to be burned or evaporated without causing any harm to the motor. Below you can see the dispersion in fuel w/ water, before and after being treated with Xp³.

Fuel **BEFORE** being treated w/ Xp³

Fuel **AFTER** being treated w/ Xp³
